Precision lab measurements on IceCube optical modules

IceCube

- In-ice Cherenkov telescope at the geographic South Pole
- 5160 DOMs containing a 10" PMT each
- Construction: 2005 – 2011
- Discovery of extra-terrestrial neutrinos: 2013

Calibrating the experiment

Hardware:

timing

gain

Quantum efficiency

resolution

noise

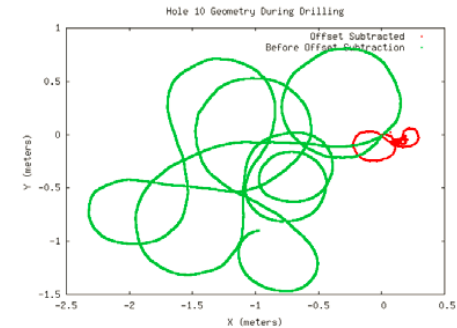

Dead time

Geometry:

DOM position

orientation

Drill data

LED data

Survey data

Muons

Ice properties:

Scattering

Absorption

Hole Ice

Flasher LEDs

cameras

muons

Dust logger

Event reconstruction:

High level stuff...

Energy resolution

Effective area

Angular resolution

→ science results

Going beyond what is required/sensible for the detector calibration...

Contents:

- The hardware, the lab

Selected properties:

- Effects of the first dynode on ...
 - ... the gain
 - ... P2V ratio
 - ... the late pulse probability
- Recovering PMT saturation
 - When?
 - How?

Nothing which is not described in the PMT bible, but still a good reminder.

BECAUSE WE CAN

The IceCube PMT and ASIC

Hamamatsu R7081-02 (datasheet):

- 10" large area PMT
 - 10 stage Box&Line dynode chain
 - 1.5 – 5% late pulsing
 - Linear to 70 mA at 2%
-
- Contained in fully independent DOM unit
 - Operated at gain 10^7

The IceCube ASIC:

Analog Transient Waveform Digitizer (ATWD) by LBNL

- 4 channels, 128 sample linear capacitor array each
- 0.3 – 3.5 analog input range
- 0.3 – 2.0 GHz sampling speed
- Acquisition triggered by comparator, digitization initialized by local coincidence → trigger
- 40 MHz, 10 bit ADC → ping-pong to reduce dead time to $< 0.1\%$

18y old ASIC

The Madison lab for absolute calibration

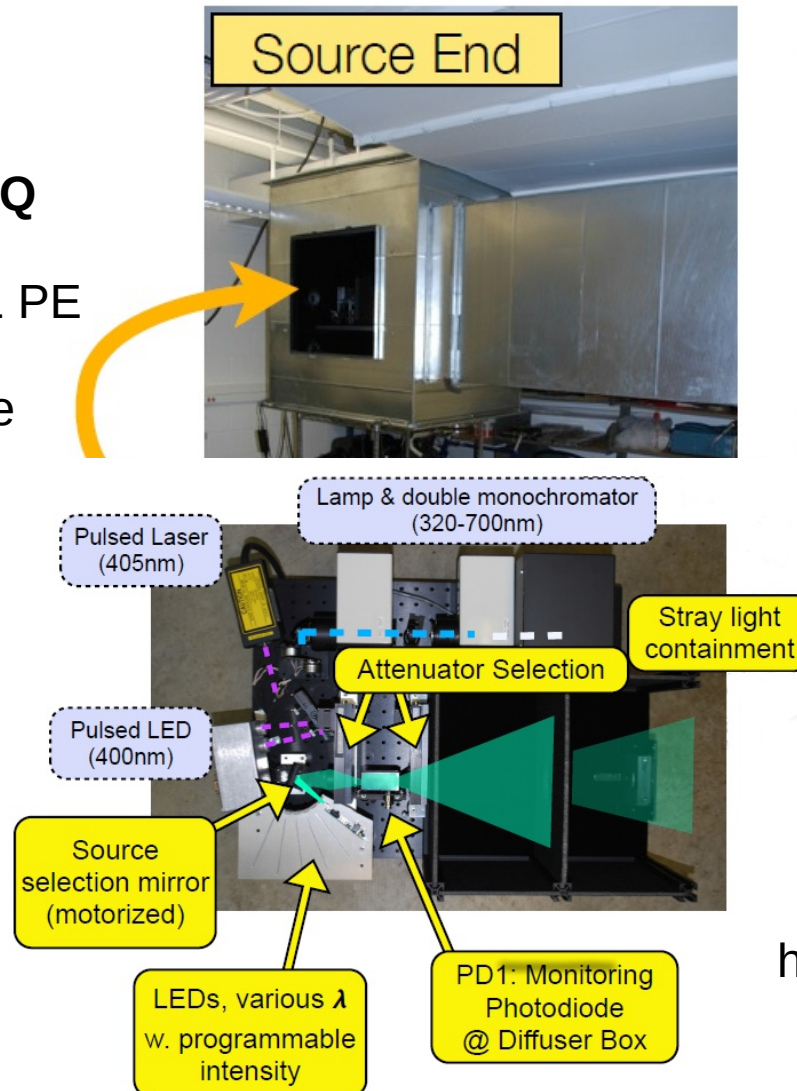

Available sources:

Pulsed → waveform DAQ

- 50ps laser with filter:
~3% chance of 1 PE
- Laser without filter:
~75 PE per pulse
- Flasher LEDs
 - High brightness
 - 30 ns
 - 1.25 us

Continuous → scalars

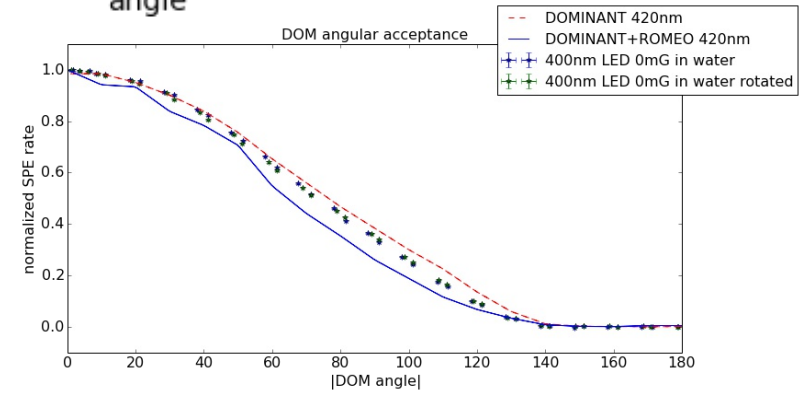

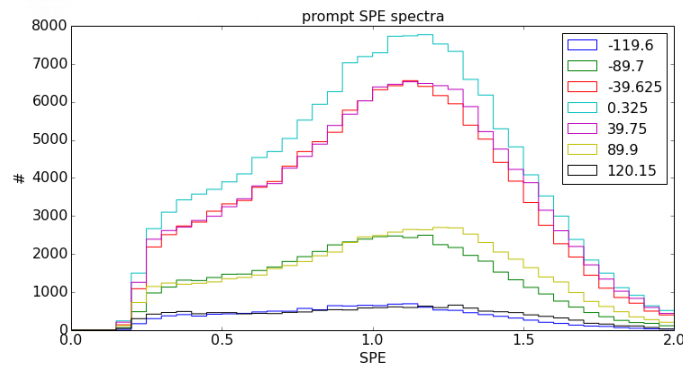

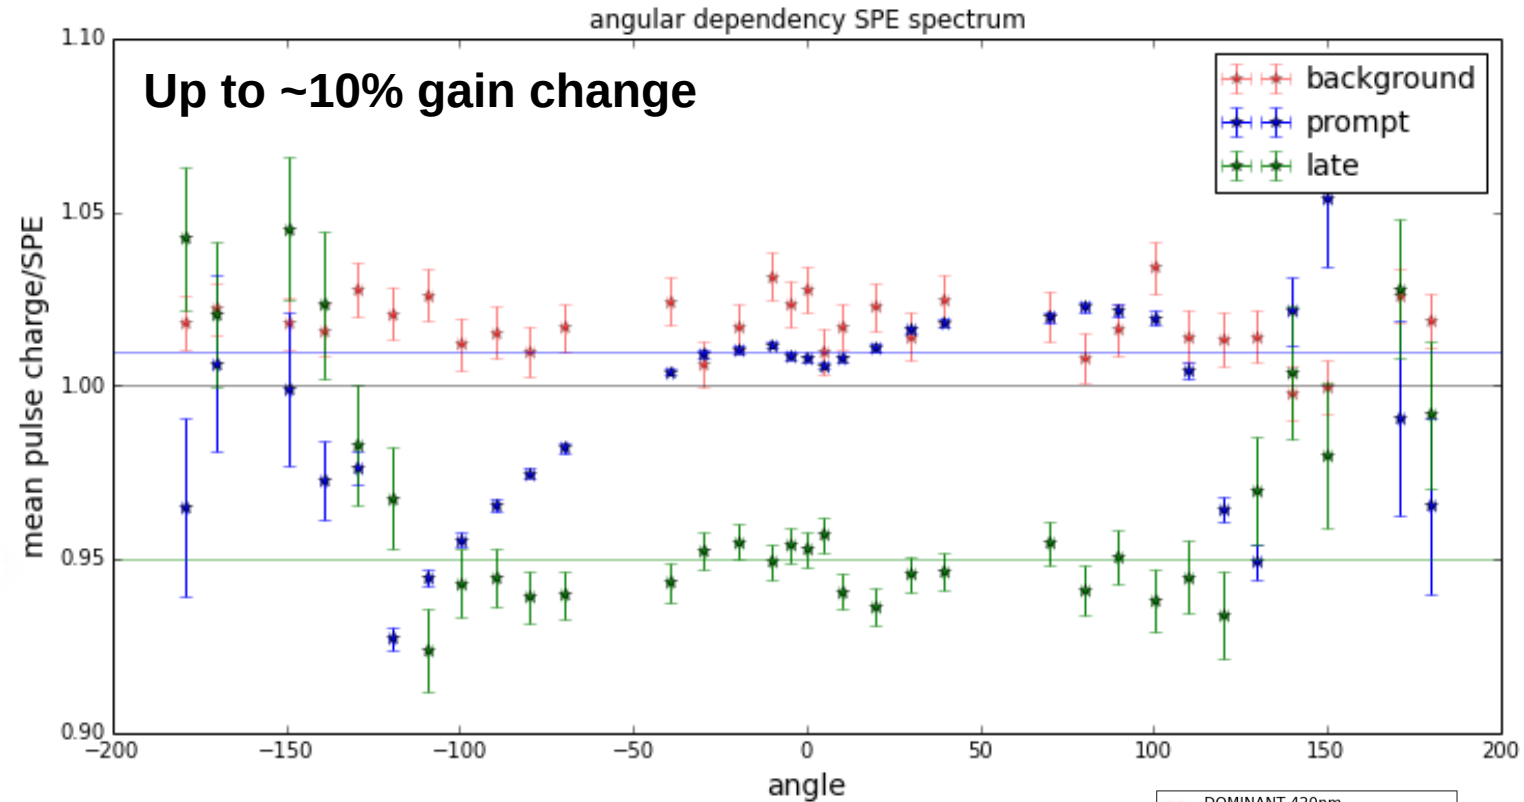

- LEDs:
 - 400 nm
 - 450 nm
 - 360 nm

Rotating the DOM

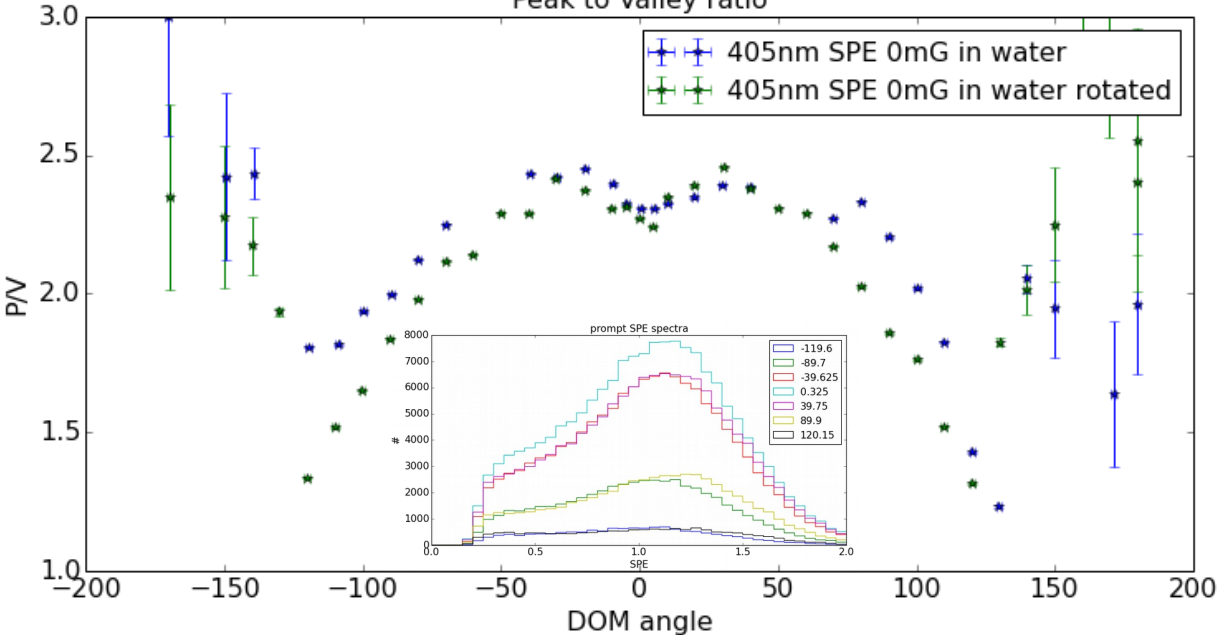

Understanding the asymmetries

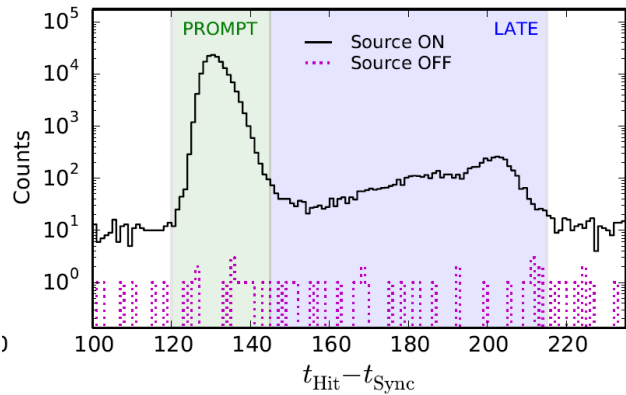

Peak to Valley ratio

As the electron optics suffers the P2V decreases.

Depending on the incident angle the scattering likelihood changes.

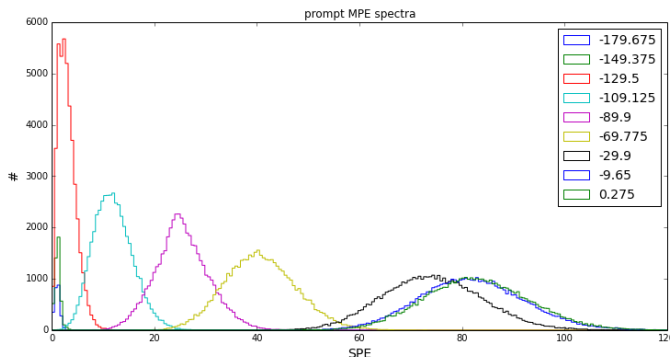

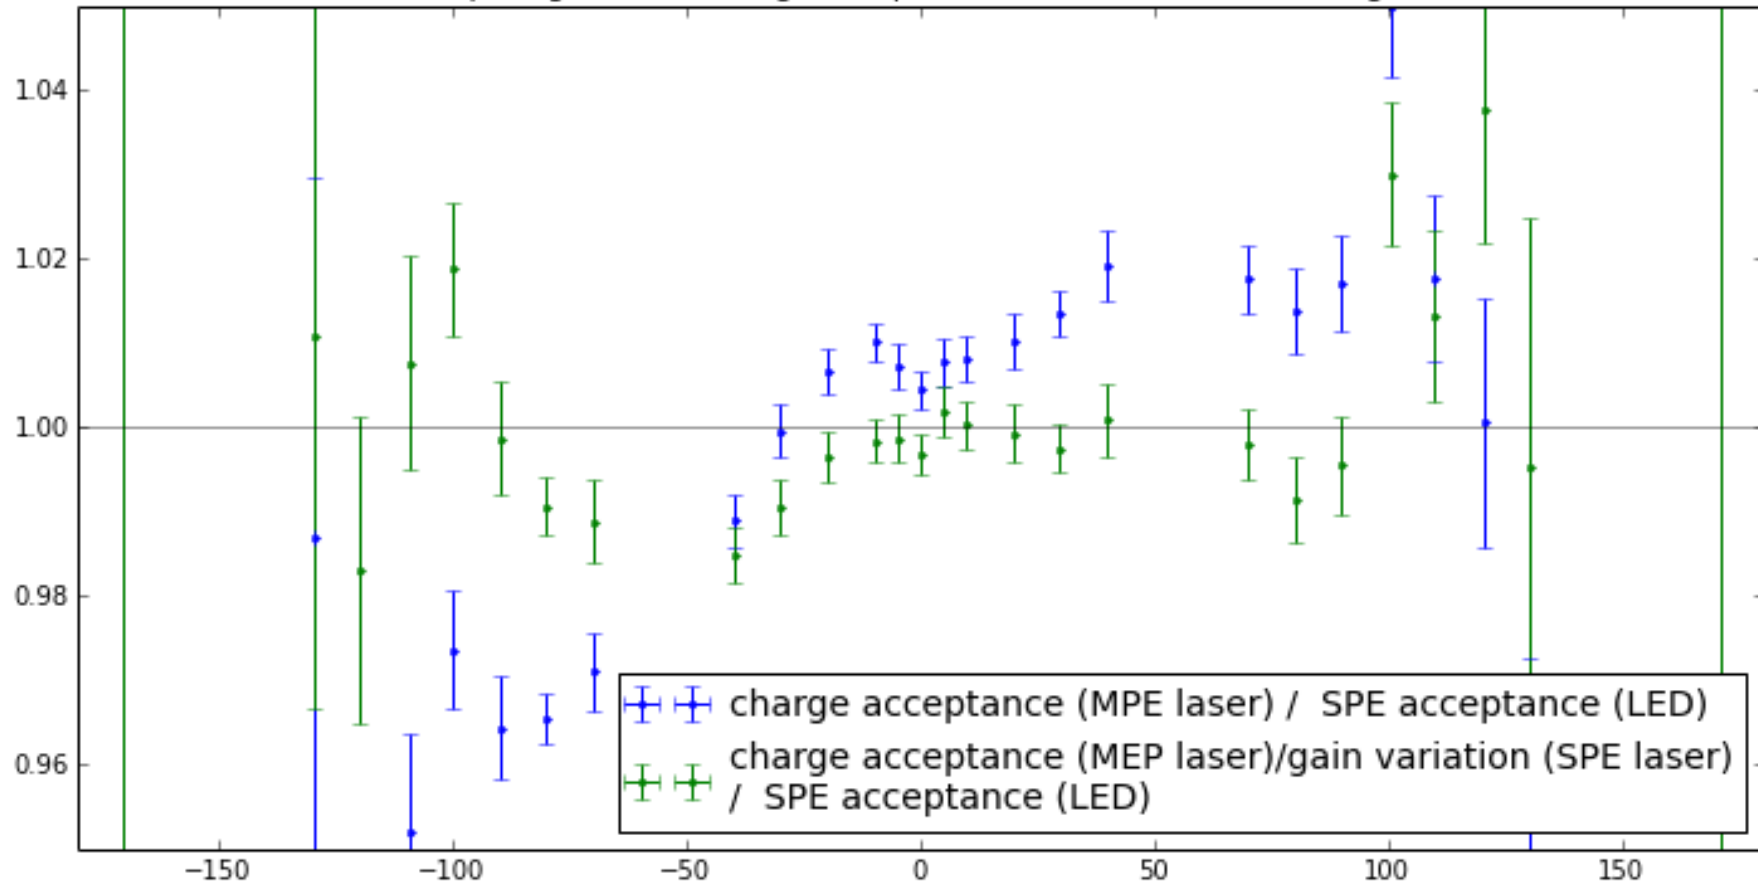

Late pulse probability

Comparing SPE and charge acceptance (each normalize to 0 degree)

DOM angle

$$\text{SPE acceptance} \approx \text{QE} * \text{CE}$$

$$\text{Charge acceptance} = \text{QE} * \text{CE} * \text{gain}$$

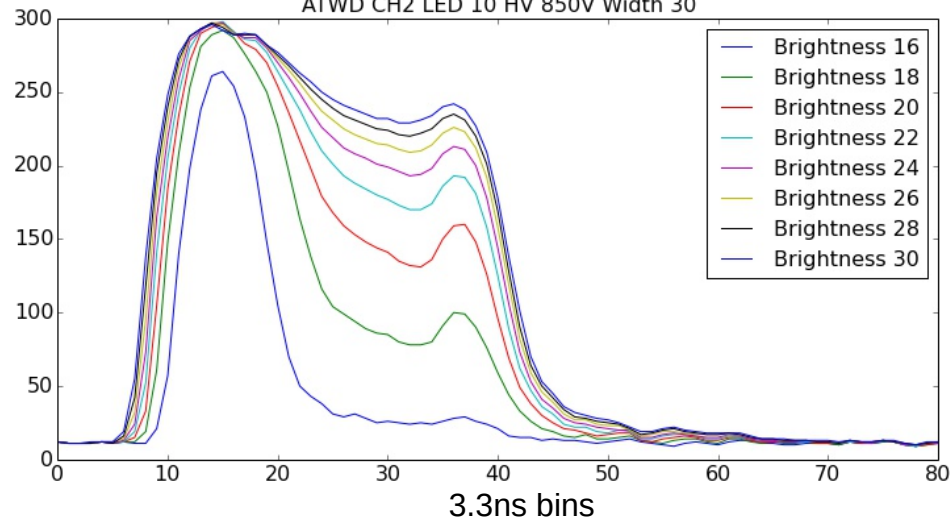

PMT saturation

PMTs can not deliver arbitrarily large instantaneous currents (space charge effects at the dynodes)

10% non-linearity reached at 50mA (31 PE/ns)

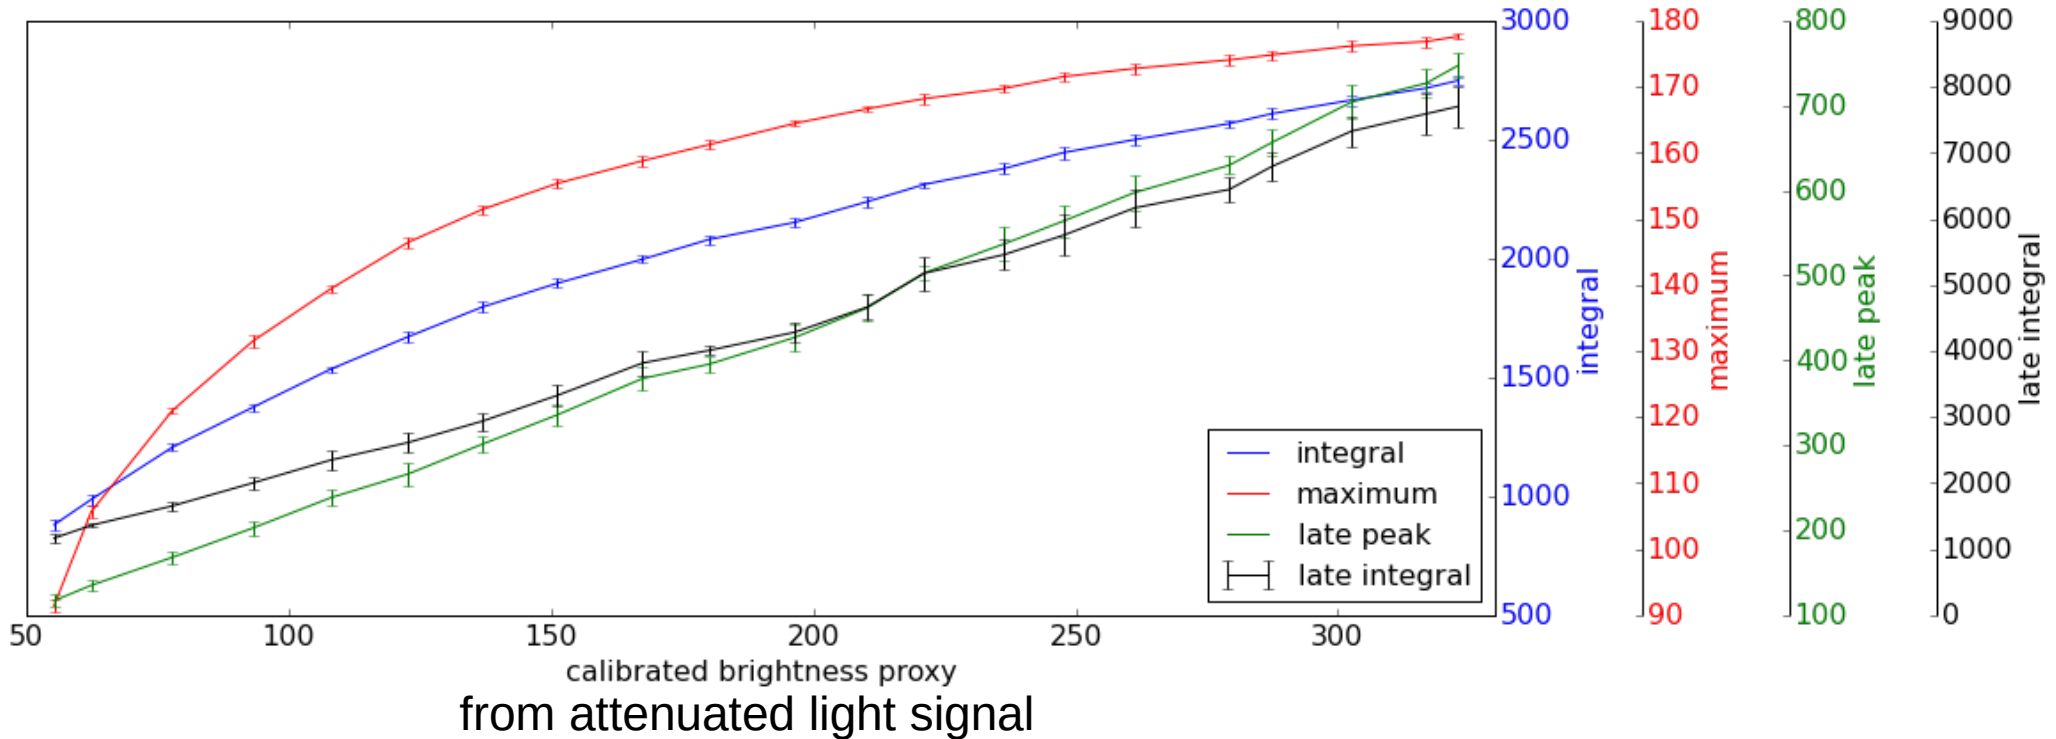

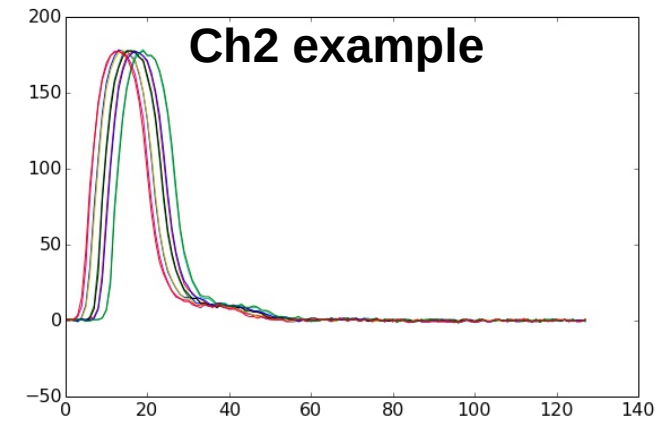

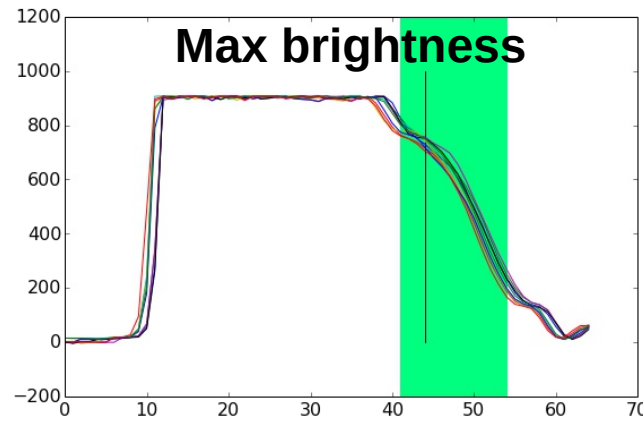

ATWD CH2 LED 10 HV 850V Width 30

PMT=AA0020

- the late pulse contains a constant fraction of the arriving photons
- recover ~ a factor 40 in pulse linearit

(But the late pulse fraction needs to be calibrated for each PMT individually...)

Thank you for your attention!
Questions are welcome

Backup

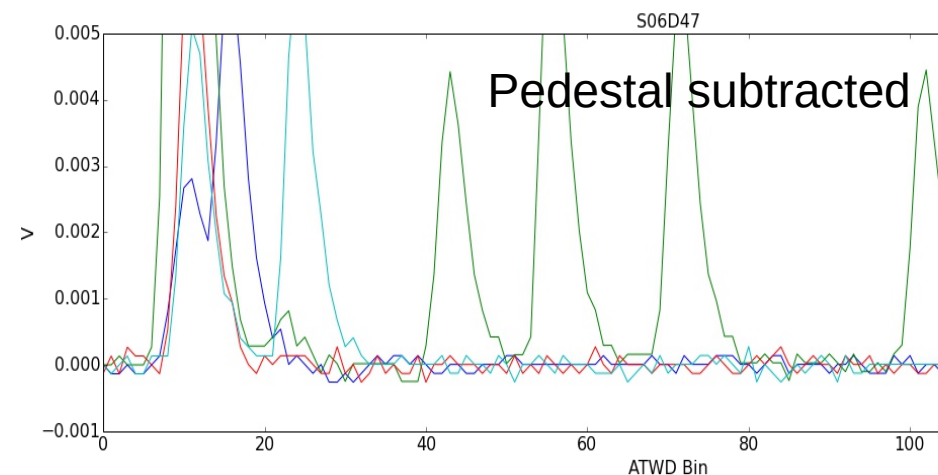

ATWD pedestals (both of them...)

ADCs work best at the mid-point of the digitization range. → A bias voltage is added to the analog signal which needs to be subtracted off. Easy!

Each capacitor in the ATWD has a slightly different parasitic charge / capacitance. The resulting constant pattern needs to be subtracted from the waveforms.

The pattern changes slightly with temperature / time. Pattern is validated with CPU clock trigger waveforms.

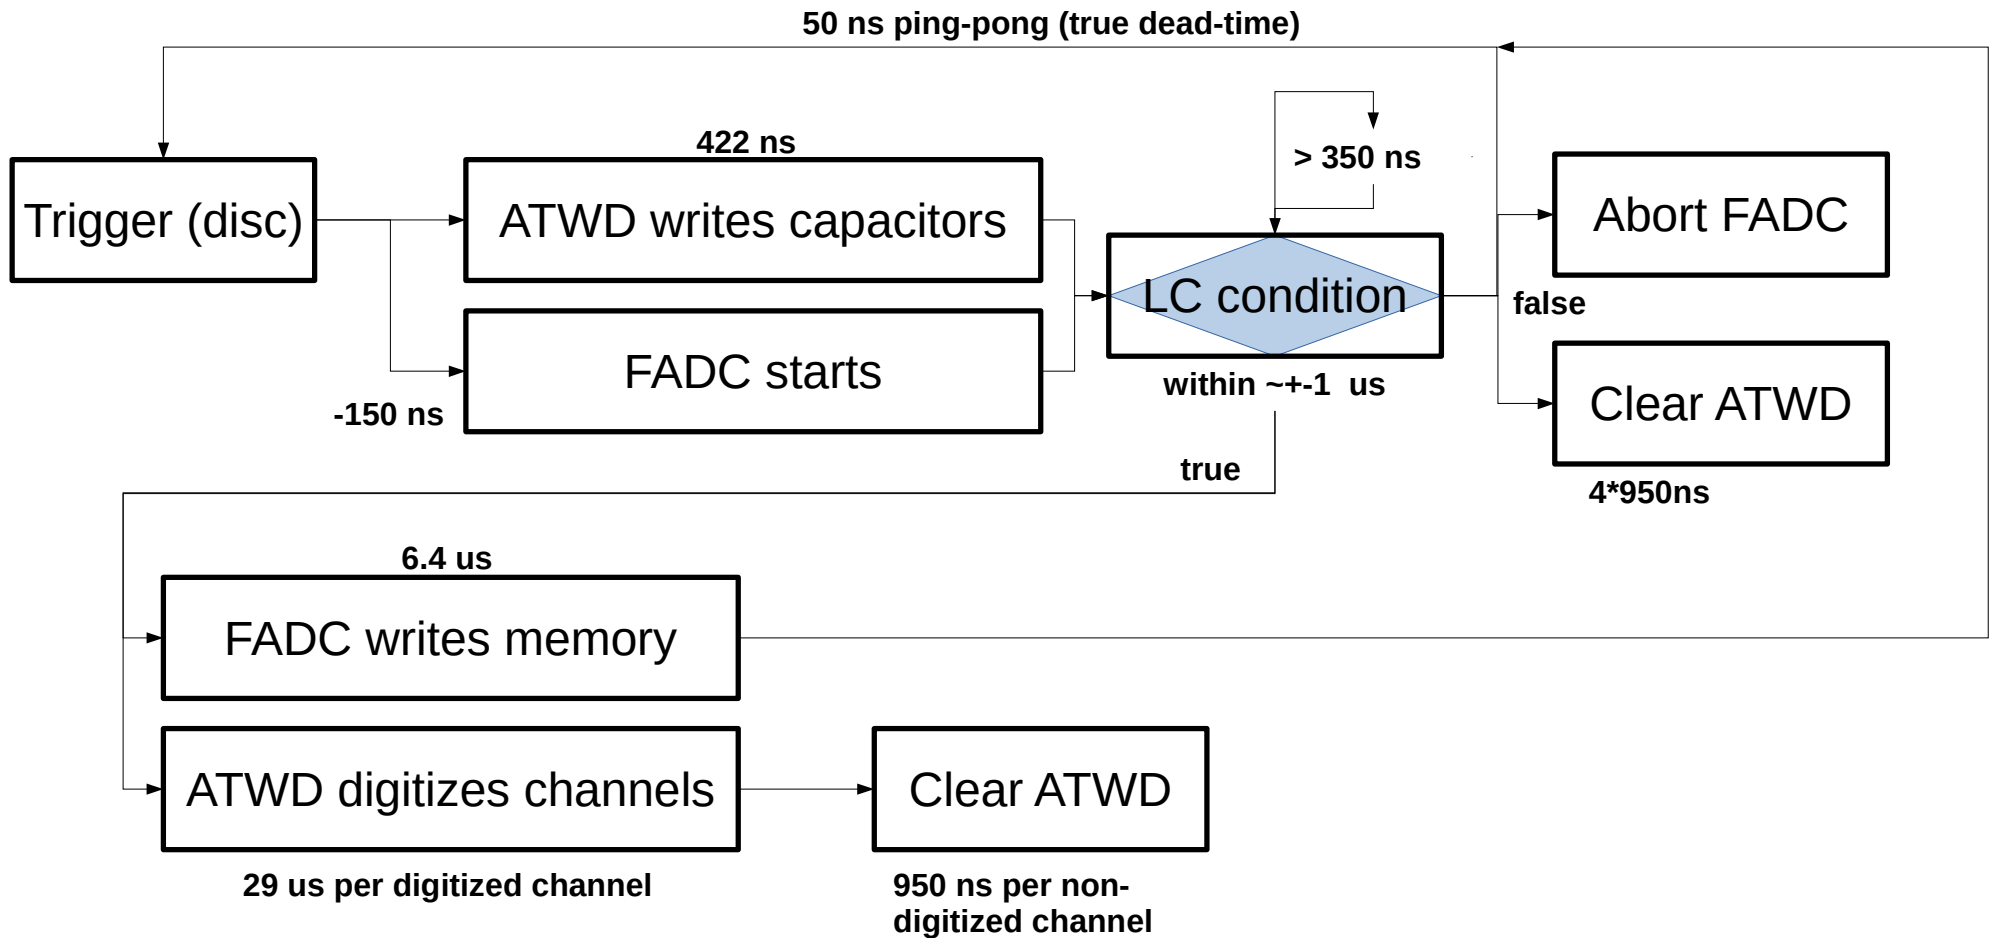

Ask Marius if you want to know what can go wrong here ;)

DAQ timing sequence

<https://docushare.icecube.wisc.edu/dsweb/Get/Document-28424>

Confusing stuff. There might be details wrong here!!

SPE charge spectra
