# EXPLORING THE LIMITS OF NEW PHYSICS AT THE LHC

---

# The Large Hadron Collider (LHC)

---

- Particle accelerator with 27km circumference
- Four different interaction points (ATLAS, CMS, LHCb, ALICE)
- Protons with energies of 6.5 TeV collide **every 25 ns** (Run 2)
- Dataflow of order **PB/s**

Source: [https://www.physi.uni-heidelberg.de/Forschung/he/ATLAS/pics-new/lhc\\_overview.png](https://www.physi.uni-heidelberg.de/Forschung/he/ATLAS/pics-new/lhc_overview.png)

# The Standard Model of Particle Physics

- Theoretical framework describing our current understanding of particle physics
- Experimental discovery of the Higgs boson at the LHC ‘completed’ the Standard Model
- Shows **great success** at describing large number of observations

# The Standard Model of Particle Physics

➤ Impressive agreement for large number of different measurements

Standard Model Production Cross Section Measurements

Status: July 2018

# The Standard Model of Particle Physics

➤ **Impressive agreement** for large number of different measurements

- **However:** Large number of unanswered questions
- Dark matter/energy
- Matter/Antimatter asymmetry
- Neutrino masses
- Strong CP problem

# Going beyond the Standard Model

- **Idea:** Introduce additional new particles (axions, sterile neutrinos, supersymmetry)
- **Problem:** Countless number of possible models to test individually
- **Solution:** Use a model agnostic approach to look for new physics

# Standard Model Effective Field Theory

➤ **Solution:** Extend the SM via a so-called Effective Field Theory approach

➤ Consider the decay:  $\mu^- \longrightarrow e^- \nu_e \nu_\mu$

Standard Model of Elementary Particles

# Standard Model Effective Field Theory

---

- SMEFT framework parametrizes the new physics in such vertices

$$\mathcal{L}_{SMEFT} = \mathcal{L}_{SM} + \sum_{d=5}^n \frac{C_i^{(d)}}{\Lambda^{d-4}} O_i^{(d)}$$

- We use these parameters to put limits on new physics:

- **Large number** of possible contributions

- Contributions depend on **processes considered**

- **Goal:** Put constraints on these contributions

# Performing statistical analyses

---

- Compute the likelihood that given data matches theory

$$\mathcal{L}_{excl} = \text{Pois}(d|p(\alpha_n, \theta_i, b)) \text{Pois}(b_{CR}|b k) \prod_i \mathcal{C}(\theta_i, \sigma_i)$$

- We use LHC data published by both the ATLAS and CMS experiments
  - For results shown here Higgs, Di-Boson and electroweak data (LEP);  
~ 400 datapoints
- Sufficiently **accurate theory predictions** are necessary
  - This is where **NEMO** comes in

# Computing theory predictions

Credit: [Stefan Hoche](#)

- Analyses require computation of **theory predictions**

# Computing theory predictions

arXiv: 2108.02803 [hep-ex]

Credit: [Stefan Hoche](#)

- Analyses require computation of complex theory predictions

# Computing theory predictions

► Earlier Example:  $\mu^- \longrightarrow e^- \nu_e \nu_\mu$

# Computing theory predictions

► For the measurement shown:

# Computing theory predictions

► For the measurement shown:

# Performing statistical analyses

---

- Compute the likelihood that given data matches theory

$$\mathcal{L}_{excl} = \text{Pois}(d|p(\alpha_n, \theta_i, b)) \text{Pois}(b_{CR}|b k) \prod_i \mathcal{C}(\theta_i, \sigma_i)$$

- Theory predictions are computed using **NEMO**
  - Large number of **different processes**
  - Effects from all **21 additional parameters** describing new physics
- **21-dimensional likelihood** now needs to be mapped
  - Use **NEMO** to run multiple Markov chains

# Results from a global SMEFT analysis

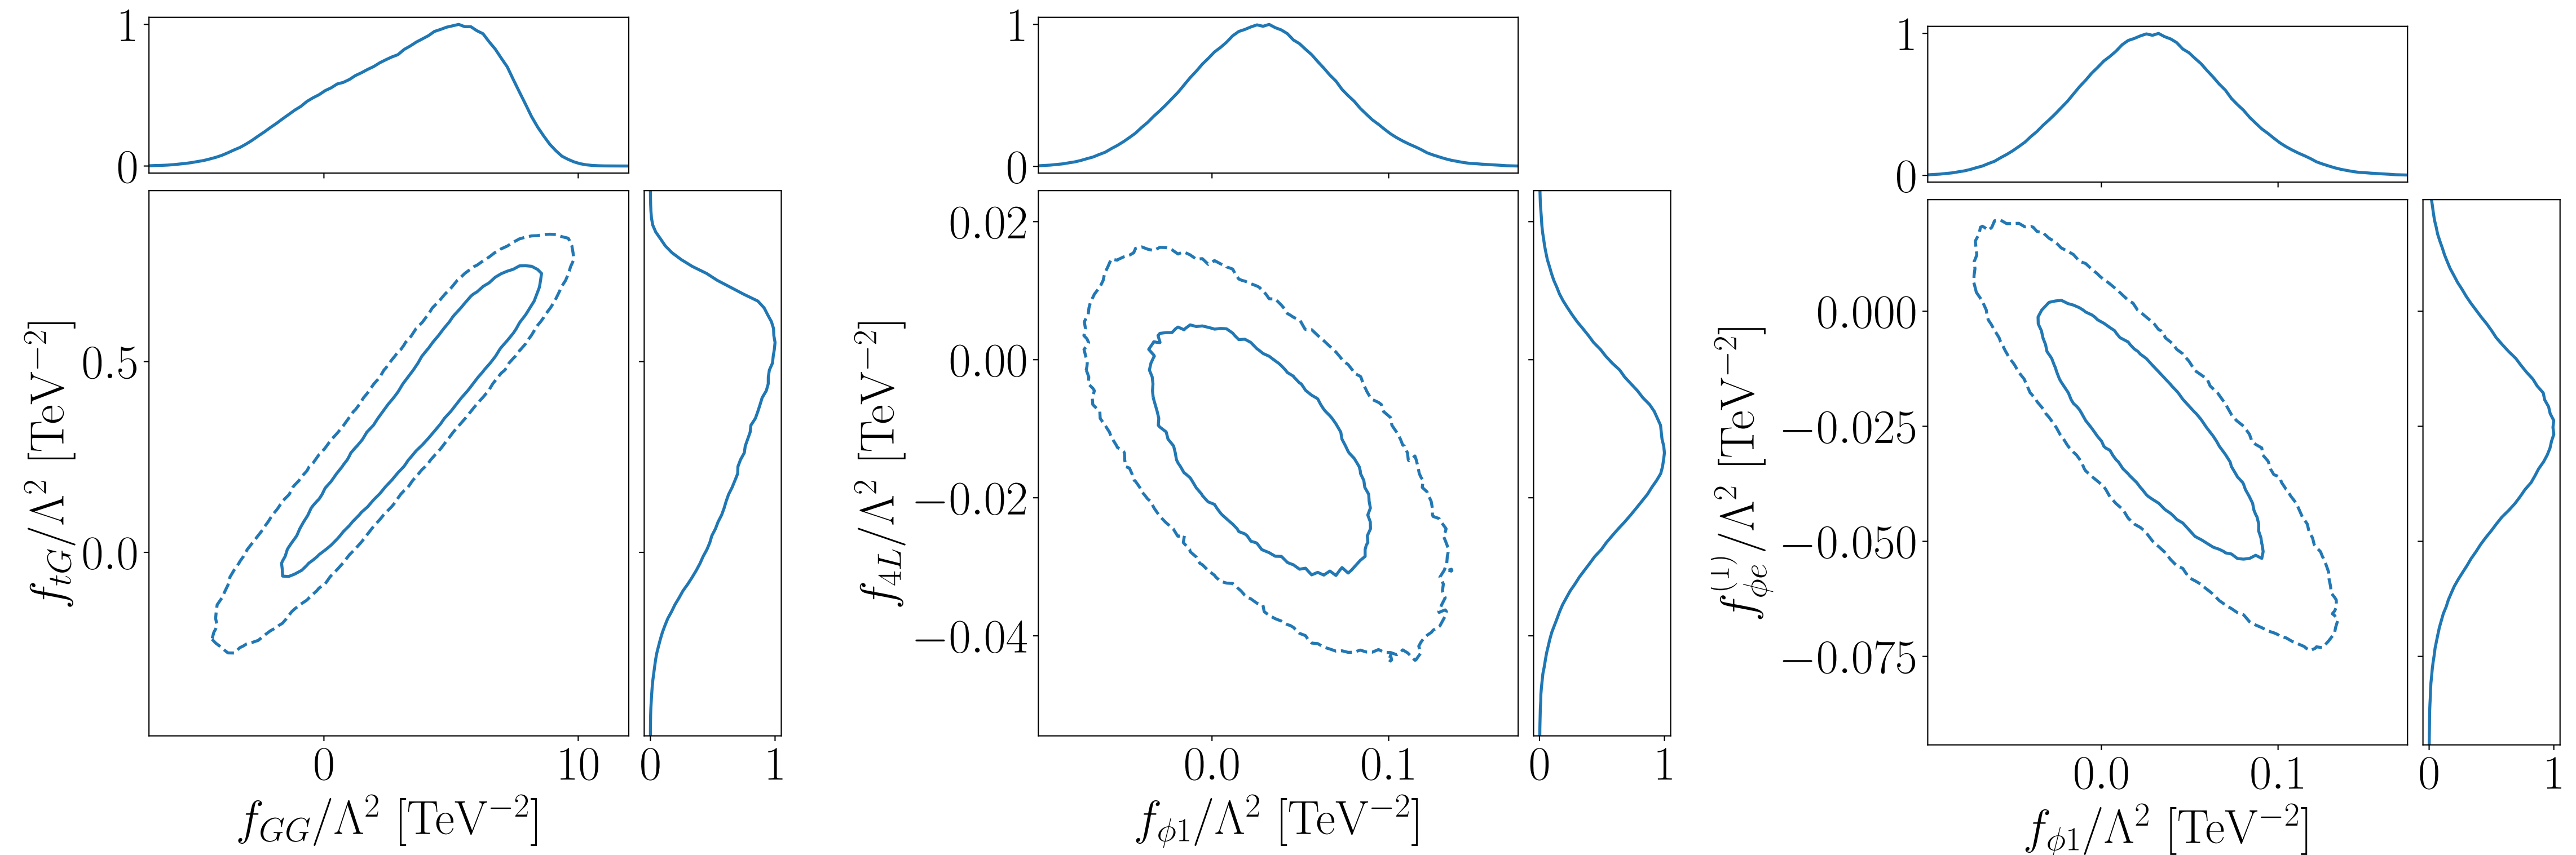

## One-dimensional results

- Each distribution describes one of the parameters for new physics effects
- Extract **limits for new physics** from these

# Results from a global SMEFT analysis

## Two-dimensional results

► Study **correlations** between different parameters

# Results from a global SMEFT analysis

## Extracted limits

➤ What do these limits tell us?

# Results from a global SMEFT analysis

---

## Matching constraints to models

► Back to our example:

Matching to model with W-Boson  
**predicts new physics at  $\approx 100$  GeV**

# Results from a global SMEFT analysis

---

## Matching constraints to models

- Back to our example:

Matching to model with W-Boson  
**predicts new physics at  $\approx 100$  GeV**

Nowadays we know:  $m_W \approx 81$  GeV

- Matching for one of our studies in [arXiv:2108.01094](https://arxiv.org/abs/2108.01094) [hep-ph]

# Outlook and Summary

---

- Where do we go from here?
  - Shown results from an analysis using 21 parameters; ~400 datapoints
  - Current work extends parameters space up to 39 and extends the dataset
- Why **NEMO** is indispensable:
  - Computation of **numerous complex theory predictions**
  - Mapping of **high-dimensional parameter spaces**

**Thank you for your attention!**
